Abstract. We compute relativistic corrections to the process $e^+e^- \rightarrow J/\psi + \eta_c$ and find that they resolve the discrepancy between theory and experiment.

The disagreement between theory and experiment for the exclusive double-charmonium process $e^+e^- \rightarrow J/\psi + \eta_c$ has, for a number of years, been one of the largest discrepancies in the standard model. The production cross section times the branching fraction into two or more charged tracks $\sigma(e^+e^- \rightarrow J/\psi + \eta_c) \times B_{>2}$, has been measured by the Belle Collaboration to be $25.6 \pm 2.8 \pm 3.4$ fb (Ref. [1]) and by the BABAR Collaboration to be $17.6 \pm 2.8^{+1.5}_{-2.1}$ fb (Ref. [2]). In contrast, nonrelativistic QCD (NRQCD) factorization [3] calculations at leading order in α_s predict cross sections of 3.78 ± 1.26 fb (Ref. [4]) and 5.5 fb (Ref. [5]). The differences between these calculations arise from different choices of m_c , NRQCD matrix elements, and α_s and from the fact that the calculation of Ref. [4] includes QED effects, while that of Ref. [5] does not. An important recent development is the calculation of the corrections of next-to-leading order in α_s (Ref. [6]), which yield a K factor of about 1.96. However, even if one includes this K factor, a significant discrepancy remains.

It is known from the work of Ref. [4] that relativistic corrections to the process are potentially large. The first relativistic correction appears at order v^2 , where v is the heavy quark or antiquark velocity in the quarkonium rest frame. ($v^2 \approx 0.3$ for charmonium.) In Ref. [4], the order- v^2 corrections are estimated to give a K factor $2.0^{+2.9}_{-1.1}$. The large uncertainties arise because of large uncertainties in the relevant nonperturbative NRQCD matrix element of relative order v^2 . If the order- v^2 K factor is indeed large, then this casts doubt on the convergence of the v expansion of NRQCD. In what follows, we address the uncertainty in the order- v^2 matrix through a potential-model calculation and the convergence of the v expansion through resummation.

The NRQCD matrix element of leading-order in v for production (or decay) of the η_c is related to the wave function at the origin $\psi(0)$:

$$\psi(0) \equiv \int \frac{d^3p}{(2\pi)^3} \tilde{\psi}(\mathbf{p}) = \frac{1}{\sqrt{2N_c}} \langle 0 | \chi^\dagger \psi | \eta_c \rangle. \quad (1)$$

Here ψ annihilates a heavy quark, $\chi^\dagger$ annihilates a heavy antiquark, and $\psi(\mathbf{x})$ and $\tilde{\psi}(\mathbf{p})$ are coordinate-space and momentum-space Schrödinger wave functions, respectively. A similar matrix element appears in NRQCD expressions for J/ψ production and decay. The corresponding NRQCD matrix elements of higher order in v^2 are given by

$$\psi^{(2n)}(0) \equiv \int \frac{d^3p}{(2\pi)^3} \mathbf{p}^{2n} \tilde{\psi}(\mathbf{p}) = \frac{1}{\sqrt{2N_c}} \langle 0 | \chi^\dagger (-\nabla^2)^n \psi | \eta_c \rangle. \quad (2)$$

We use the following notation for such matrix elements: $\langle \mathbf{p}^{2n} \rangle \equiv \psi^{(2n)}(0)/\psi(0)$ and $\langle v^2 \rangle = \langle \mathbf{p}^2 \rangle / m_c^2$. Previous attempts to determine $\psi^{(2)}(0)$ from phenomenology, from lattice measurements, and from the Gremm-Kapustin relation [7] have resulted in large uncertainties. Even the sign of $\psi^{(2)}(0)$ is not known with great confidence from these methods.

Our strategy is to use a potential-model calculation, with the Cornell potential [8], to determine $\psi^{(2)}(0)$. Details of this calculation can be found in Ref. [9]. If the model potential is the exact static QQ potential, then the errors in the potential model are of relative order v^2 (Ref. [10]). With an appropriate choice of parameters, the Cornell potential provides a good fit to lattice data for the static QQ potential.

The matrix element $\psi^{(2)}(0)$ contains a linear UV divergence and must be regulated. Because existing calculations in NRQCD of order α_s and higher make use of dimensional regularization, we ultimately want to obtain a dimensionally regulated matrix element. We introduce two methods to achieve this.

Method 1 requires knowledge only of the wave function. In this method, we first regulate using a simple, analytic momentum-space hard cutoff $\Lambda^2/(\mathbf{p}^2 + \Lambda^2)$. Then, we calculate the difference between $\psi^{(2)}(0)$ in hard-cutoff and dimensional regularization, which we call $\Delta\psi^{(2)}(0)$. Since $\Delta\psi^{(2)}(0)$ gives the difference between UV regulators, it is dominated by large momenta and can be computed in perturbation theory. We subtract $\Delta\psi^{(2)}(0)$ from the hard-cutoff result. In order to obtain the dimensionally regulated result, we must extrapolate this subtracted expression to $\Lambda = \infty$ because our computation of $\Delta\psi^{(2)}(0)$ does not include contributions that are suppressed as $1/\Lambda$.

Method 2 is applicable only to potential models. It requires knowledge of the binding energy and the potential, in addition to the wave function. In this approach, we use the Bethe-Salpeter equation to expose an explicit loop from the wave function in the expression for the matrix element. Then, we regulate that loop dimensionally. The result is equal to that which would be obtained from the Gremm-Kapustin relation, but for the binding energy of the potential model.

The results from Method 1 and Method 2 agree well numerically and yield $\psi^{(2)}(0) = 0.118 \pm 0.024 \pm 0.035 \text{ GeV}^{7/2}$ and $\langle \mathbf{p}^2 \rangle = 0.50 \pm 0.09 \pm 0.15 \text{ GeV}^2$, which imply for $m_c = 1.4 \text{ GeV}$ that $\langle v^2 \rangle \approx 0.25 \pm 0.05 \pm 0.08$. This last result is in good agreement with

expectations from the NRQCD v -scaling rules. In all of these results, the first error bar reflects the uncertainty in the input potential-model parameters and the wave function at the origin, and the second error bar reflects relative-order- v^2 corrections that have been neglected. This is the first determination of $\psi^{(2)}(0)$ with small enough uncertainties to be useful phenomenologically.

We can extend Method 2 to matrix elements of higher order in v . By using the equation of motion, dimensional regularization, and the scalelessness of the individual terms in the Cornell potential, we obtain the simple relation

$$\langle \mathbf{p}^{2n} \rangle = \langle \mathbf{p}^2 \rangle^n. \quad (3)$$

This relation allows one to resum a class of the relativistic corrections to S -wave quarkonium decay and production amplitudes to all orders in v .

We now apply these results to the relativistic corrections to $\sigma[e^+e^- \rightarrow J/\psi + \eta_c]$. These corrections arise in two ways. First, they appear directly in the process $e^+e^- \rightarrow J/\psi + \eta_c$ itself. Second, they enter indirectly through $|\psi(0)|^2$, which appears as a factor in the contribution of leading order in v^2 . The quantity $|\psi(0)|^2$ is determined from the experimental value for the width for $J/\psi \rightarrow e^+e^-$ and the theoretical expression for that process, which is affected by relativistic corrections.

Our preliminary results, including the effects of QED, as well as QCD, contributions are as follows. The resummed relativistic corrections to $\sigma[e^+e^- \rightarrow J/\psi + \eta_c]$ itself yield a K factor 1.34, while the resummed relativistic corrections to $|\psi(0)|^2$ yield a K factor 1.32. In both cases, the resummation of contributions beyond order v^2 has only about a 10% effect on the K factors, which indicates that v expansion of NRQCD converges well for these processes. Combining the resummed relativistic-correction K factors with the relative-order- α_s K factor 1.96, we obtain a complete K factor 4.15. Applying this to the calculation of Ref. [4] and using the most recent value for $\Gamma[J/\psi \rightarrow e^+e^-]$ (Ref. [11]), we obtain a prediction $\sigma[e^+e^- \rightarrow J/\psi + \eta_c] = 17.5 \pm 5.7$ fb. The quoted uncertainty reflects only the uncertainties in the values of m_c and $\langle \mathbf{p}^2 \rangle$. Other theoretical uncertainties are large and need to be quantified. Nevertheless, our prediction is in agreement with the Belle and BABAR results, and it seems that the inclusion of relative-order- α_s and relativistic corrections resolves the discrepancy between theory and experiment at the present level of precision.
